CS389L: Automated Logical Reasoning Lecture 13: The Omega Test

1/34

Theory of Integers

- ▶ This lecture: Decision procedure for qff theory of integers
- ▶ As in previous two lectures, we'll consider $T_{\mathbb{Z}}$ formulas without disjunctions
- ▶ **Problem we want to solve:** Given an $m \times n$ matrix A with only integer coefficients and a vector \vec{b} in \mathbb{Z}^n , does

$$A\vec{x} \leq \vec{b}$$

have any **integer** solutions?

- ▶ Integrality requirement actually makes problem much harder
- ▶ Finding solution over rationals is poly-time, but integer problem is NP-complete even without disjunctions

Işıl Dillig

CS389L: Automated Logical Reasoning Lecture 13: The Omega Test

2/34

Geometric Description

- ▶ As before the system $A\vec{x} \leq \vec{b}$ defines a polytope
- ▶ Last time we asked the question: Is the polytope empty?
- ▶ This time, we want to know if polytope contains integer points
- ▶ While the polytope is convex, the space formed by all integer points in polytope is **not convex**
- ▶ Unfortunately, non-convexity makes problem much harder to solve

Işıl Dillig

CS389L: Automated Logical Reasoning Lecture 13: The Omega Test

3/34

Overview of Techniques

- ▶ Two different techniques for solving linear integer inequalities
 1. **Elimination-based techniques:** Eliminate variables one by one until system becomes trivially solvable (e.g., Omega Test, Cooper's method)
 2. **Relaxation-based techniques:** Drop integrality requirement and iteratively add constraints (e.g., Branch-and-bound, Gomory cuts, Cuts-from-Proofs)
- ▶ Plan: Talk about an elimination-based method today; talk about relaxation-based methods next time

Işıl Dillig

CS389L: Automated Logical Reasoning Lecture 13: The Omega Test

4/34

The Omega Test: Historical Perspective

- ▶ Omega Test: invented in early 1990's for compiler optimizations
- ▶ Particular application: **array dependence analysis**
- ▶ Array dependence analysis: "Can two expressions $a[i]$ and $a[j]$ refer to same element?"
- ▶ Can use this information to reorder read and writes from the array and perform operations in parallel

Işıl Dillig

CS389L: Automated Logical Reasoning Lecture 13: The Omega Test

5/34

Array Dependence Analysis Example

- ▶ Consider the following code snippet:

```
for(i=1; i<= 100; i++) {
  for(j=i; j<= 100; j++)
    a[i, j+1] = a[100, j]
}
```

- ▶ Can the expressions $a[i, j+1]$ and $a[100, j]$ ever refer to same element (not necessarily in same iteration)? **No!**
- ▶ Thus, no array element is both read and written to in the loop
- ▶ Hence, we can optimize code by performing assignments in parallel!

Işıl Dillig

CS389L: Automated Logical Reasoning Lecture 13: The Omega Test

6/34

Array Dependence Analysis as Integer Constraints

```
for(i=1; i<= 100; i++) {
  for(j=i; j<= 100; j++)
    a[i, j+1] = a[100, j]
}
```

- ▶ Can express dependence analysis as linear integer constraints
- ▶ Variables w_i and w_j denote array indices when write is performed
- ▶ Variables r_i and r_j denote array indices when read is performed
- ▶ How do we express that same element is both read and written to? $w_i = r_i \wedge w_j = r_j$

Işıl Dillig

CS389L: Automated Logical Reasoning Lecture 13: The Omega Test

7/34

Array Dependence Analysis as Integer Constraints, cont

```
for(i=1; i<= 100; i++) {
  for(j=i; j<= 100; j++)
    a[i, j+1] = a[100, j]
}
```

- ▶ Based on loop start/end conditions, what are constraints on w_i ? $1 \leq w_i \leq 100$
- ▶ What are constraints on w_j ? $w_i < w_j \leq 101$
- ▶ What are constraints on r_i ? $r_i = 100$
- ▶ What are constraints on r_j ? $w_i \leq r_j \leq 100$

Işıl Dillig

CS389L: Automated Logical Reasoning Lecture 13: The Omega Test

8/34

Array Dependence Analysis as Integer Constraints, cont

- ▶ Thus, an array element may be both read and written in the loop if the conjunction of these constraints is satisfiable:

$$\begin{aligned} w_i &= r_i \wedge w_j = r_j \\ 1 \leq w_i \leq 100 \wedge w_i < w_j \leq 101 \\ r_i &= 100 \wedge w_i \leq r_j \leq 100 \end{aligned}$$

- ▶ Since array indices can't be real numbers, only interested in **integer solution**
- ▶ Since this constraint has no integer solutions, there is no dependence between array reads and writes
- ▶ Thus, all writes can be done in parallel

Işıl Dillig

CS389L: Automated Logical Reasoning Lecture 13: The Omega Test

9/34

Applications of Theory of Integers

- ▶ Array dependence analysis one application of decision procedure for theory of integers
- ▶ Omega Test was initially invented to do better job with array dependence analysis
- ▶ Many other applications in software verification, compiler optimizations, operations research, ...

Işıl Dillig

CS389L: Automated Logical Reasoning Lecture 13: The Omega Test

10/34

Omega Test: Main Idea

- ▶ **Main idea:** Eliminate variables one by one from the initial system $A\vec{x} \leq \vec{b}$
- ▶ Geometrically, eliminating a variable corresponds to computing a projection of a polytope in n -dimensional space to an $n - 1$ -dimensional space
- ▶ Since the polytope has one less dimension at each step, resulting problem is easier to solve than the previous one

Işıl Dillig

CS389L: Automated Logical Reasoning Lecture 13: The Omega Test

11/34

Projections in Omega Test

Omega test computes three kind of projections, called **shadows**:

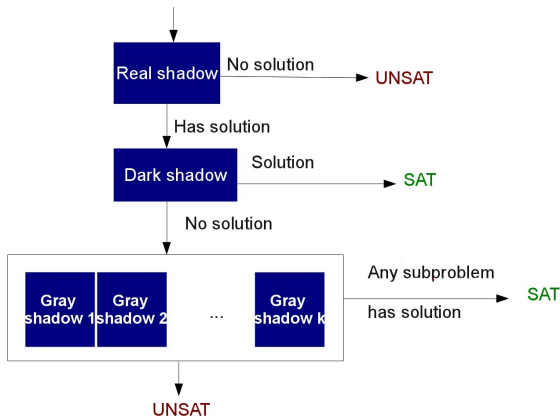

1. **Real Shadow**
 - ▶ Overapproximates satisfiability over integers
 - ▶ If real shadow has no solutions, neither does original problem
2. **Dark Shadow**
 - ▶ Underapproximates satisfiability over integers
 - ▶ If dark shadow has solution, original problem has solution
3. **Gray Shadows**
 - ▶ These correspond to areas between real and dark shadow that might contain integer points
 - ▶ Omega test constructs multiple gray shadows

Işıl Dillig

CS389L: Automated Logical Reasoning Lecture 13: The Omega Test

12/34

Omega Test Work Flow

The Real Shadow

- ▶ When constructing the real shadow, we ignore requirement that solution must be integer
- ▶ Thus, resulting projection overapproximates satisfiability of original problem
- ▶ To construct real shadow, we use the **Fourier-Motzkin** variable elimination technique

Fourier-Motzkin Variable Elimination

- ▶ Suppose we want to eliminate variable x_n from $A\vec{x} \leq \vec{b}$
- ▶ Consider an inequality $\sum_{j=1}^n a_{ij}x_j \leq b_i$
- ▶ This can be rewritten as $a_{in}x_n \leq b_i - \sum_{j=1}^{n-1} a_{ij}x_j$
- ▶ If a_{in} is positive, this yields an upper bound on x_n :

$$x_n \leq \frac{b_i}{a_{in}} - \sum_{j=1}^{n-1} \frac{a_{ij}}{a_{in}}x_j$$

- ▶ If a_{in} is negative, this yields lower bound on x_n :

$$x_n \geq \frac{b_i}{a_{in}} - \sum_{j=1}^{n-1} \frac{a_{ij}}{a_{in}}x_j$$

Fourier-Motzkin Variable Elimination, cont.

- ▶ Thus, if we have $A\vec{x} \leq \vec{b}$ has two rows i and k with positive and negative coefficients for x_n , this yields the inequality:

$$\frac{b_k}{a_{kn}} - \sum_{j=1}^{n-1} \frac{a_{kj}}{a_{kn}}x_j \leq x_n \leq \frac{b_i}{a_{in}} - \sum_{j=1}^{n-1} \frac{a_{ij}}{a_{in}}x_j$$

- ▶ We eliminate x_n by removing it from the middle of inequality:

$$\frac{b_k}{a_{kn}} - \sum_{j=1}^{n-1} \frac{a_{kj}}{a_{kn}}x_j \leq \frac{b_i}{a_{in}} - \sum_{j=1}^{n-1} \frac{a_{ij}}{a_{in}}x_j$$

- ▶ If we do this for **every** pair of inequalities with positive and negative coefficients for x_n , this yields the real shadow

Fourier-Motzkin Example

- ▶ Consider the set of inequalities:

$$x \leq y + 10 \quad y \leq 15 \quad -x + 20 \leq y$$

- ▶ Let's compute real shadow on x -axis using Fourier-Motzkin
- ▶ Isolate y on one side:

$$(1) \ x - 10 \leq y \quad (2) \ y \leq 15 \quad (3) \ -x + 20 \leq y$$

- ▶ From (1) and (2), we get $x - 10 \leq 15$, i.e., $x \leq 25$
- ▶ From (2) and (3), we get $-x + 20 \leq 15$, i.e. $x \geq 5$
- ▶ Thus, real shadow on x -axis is $5 \leq x \leq 25$

Dark Shadow

- ▶ The second projection Omega test constructs is **dark shadow**
- ▶ Dark shadow underapproximates satisfiability
- ▶ Suppose we want to eliminate variable x from $A\vec{x} \leq \vec{b}$
- ▶ Dark shadow only projects those parts of polytope that are **at least one unit thick** in the x -dimension
- ▶ If dark shadow has integer solution, original polytope must also have integer solution. Why?
- ▶ Since polytope is at least one unit thick above the dark shadow in x -dimension, we are guaranteed to have an integer solution for x as well!

Math Behind the Dark Shadow

- ▶ As in real shadow, consider a pair of inequalities corresponding to lower and upper bounds on x :

$$\mathcal{L} \leq ax \quad bx \leq \mathcal{U}$$

- ▶ These imply:

$$\frac{\mathcal{L}}{a} \leq x \leq \frac{\mathcal{U}}{b}$$

- ▶ Now, suppose there is no integer between $\frac{\mathcal{L}}{a}$ and $\frac{\mathcal{U}}{b}$
- ▶ Consider first integer i smaller than $\frac{\mathcal{L}}{a}$

Math Behind the Dark Shadow, cont.

- ▶ Thus, we have the following inequalities:

$$\frac{\mathcal{L}}{a} - i \geq \frac{1}{a}$$

$$i + 1 - \frac{\mathcal{U}}{b} \geq \frac{1}{b}$$

- ▶ If we sum these up, we get:

$$\frac{\mathcal{L}}{a} - \frac{\mathcal{U}}{b} + 1 \geq \frac{1}{a} + \frac{1}{b}$$

Math Behind Dark Shadow, cont

- ▶ If we rearrange this equation, we get:

$$b\mathcal{L} - a\mathcal{U} \geq b + a - ab$$

- ▶ Finally, multiplying both sides by -1 :

$$a\mathcal{U} - b\mathcal{L} \leq ab - a - b \quad (*)$$

- ▶ **Recall:** We derived this equation by assuming that there is no integer solution for x
- ▶ That is, we showed "If there is no integer solution for x , then $(*)$ must hold"
- ▶ Thus, **negation** of $(*)$ guarantees there **exists integer solution** for x !

Math Behind Dark Shadow, cont

- ▶ Thus, negation of $(*)$

$$a\mathcal{U} - b\mathcal{L} > ab - a - b \quad (**)$$

guarantees there is an integer value for x !

- ▶ Thus, to construct dark shadow, we remove inequalities containing x and add inequality $(**)$
- ▶ Resulting projection is underapproximation because only projects those parts that are at least one unit thick, but there might be an integer solution for x even if it's not unit thick

Dark Shadow Example

- ▶ Compute the dark shadow of these inequalities on the x -axis

$$(1) 4y \geq x \quad (2) 2y \geq 6 - 3x \quad (3) 3y \leq 7 - x$$

- ▶ Using (1), (3), we have $a = 4, \mathcal{L} = x$ and $b = 3, \mathcal{U} = 7 - x$:

$$4(7 - x) - 3x > 12 - 4 - 3 \Rightarrow x < \frac{23}{7}$$

- ▶ Using (2), (3), we have $a = 2, \mathcal{L} = 6 - 3x$ and $b = 3, \mathcal{U} = 7 - x$:

$$2(7 - x) - 3(6 - 3x) > 6 - 3 - 2 \Rightarrow x > \frac{5}{7}$$

- ▶ What can we conclude based on dark shadow?

Dark Shadow Geometrically

- ▶ Compute the dark shadow of these inequalities on the x -axis

$$(1) 4y \geq x \quad (2) 2y \geq 6 - 3x \quad (3) 3y \leq 7 - x$$

- ▶ Geometrically:

Gray Shadows

- ▶ **Recall:** Real shadow overapproximates the problem, and dark shadow underapproximates it.
- ▶ If real shadow has integer solutions, but dark shadow does not, we still don't know if original problem has integer solutions.
- ▶ In this case, Omega test constructs projections called **gray shadows**
- ▶ Gray shadows look for integer solutions **outside** the dark shadow, but **inside** the real shadow.

Işıl Dillig

CS389L: Automated Logical Reasoning Lecture 13: The Omega Test

25/34

Constructing the Gray Shadow

- ▶ Consider again the pair of inequalities:

$$\mathcal{L} \leq ax \quad bx \leq \mathcal{U}$$

- ▶ By construction, any point **in the real shadow** satisfies:

$$b\mathcal{L} \leq abx \leq a\mathcal{U} \quad (1)$$

- ▶ Also, by construction, any point **outside dark shadow** satisfies:

$$a\mathcal{U} - b\mathcal{L} \leq ab - a - b$$

- ▶ We can rewrite above as: $a\mathcal{U} \leq b\mathcal{L} + ab - a - b$ (2)

- ▶ Combining (1) and (2), we have:

$$b\mathcal{L} \leq abx \leq b\mathcal{L} + ab - a - b$$

Işıl Dillig

CS389L: Automated Logical Reasoning Lecture 13: The Omega Test

26/34

Constructing Gray Shadow, cont.

- ▶ Thus, any point inside real shadow but outside dark shadow must satisfy:

$$b\mathcal{L} \leq abx \leq ab + b\mathcal{L} - a - b$$

- ▶ Dividing by b , points in the gray shadow must satisfy:

$$\mathcal{L} \leq ax \leq \mathcal{L} + \frac{ab - a - b}{b}$$

- ▶ **Observe:** If x is an integer, ax must also be integer
- ▶ Furthermore, ax must be equal to

$$\mathcal{L} + i$$

for some i in the range $[0, \frac{ab-a-b}{b}]$

Işıl Dillig

CS389L: Automated Logical Reasoning Lecture 13: The Omega Test

27/34

Constructing Gray Shadow, cont.

- ▶ Thus, we construct each gray shadow by adding the equality:

$$ax = \mathcal{L} + i$$

for **each** i in the range $[0, \frac{ab-a-b}{b}]$

- ▶ If any subproblem has integer solution, then so does original problem
- ▶ If no subproblem has integer solution, original problem unsatisfiable

Işıl Dillig

CS389L: Automated Logical Reasoning Lecture 13: The Omega Test

28/34

Remark about Gray Shadows

- ▶ **Observe:** If there are n integers between 0 and $\frac{ab-a-b}{b}$, Omega test constructs n gray shadows
- ▶ Thus, Omega test is **very sensitive** to coefficients in formula
- ▶ The larger a is, the more gray shadows we must consider
- ▶ **Nightmare for Omega test:** Real shadow has solution, dark shadow has no solution, and coefficient a is very large, and problem is unsatisfiable

Işıl Dillig

CS389L: Automated Logical Reasoning Lecture 13: The Omega Test

29/34

Gray Shadow Example

- ▶ Consider these inequalities:

$$(1) 5y \leq 3x + 3 \quad (2) 4y \leq 9 - 2x \quad (3) 4y \geq 3$$

- ▶ Real shadow: $\frac{1}{4} \leq x \leq 3$

- ▶ Dark shadow: $\frac{15}{12} \leq x \leq \frac{15}{8}$

- ▶ Do we need to consider gray shadows?

Işıl Dillig

CS389L: Automated Logical Reasoning Lecture 13: The Omega Test

30/34

Gary Shadow Example, cont.

- ▶ Consider these inequalities:

$$(1) 5y \leq 3x + 3 \quad (2) 4y \leq 9 - 2x \quad (3) 4y \geq 3$$

- ▶ Derive gray shadow using constraints (1) and (3)

$$5y \leq 3x + 3 \quad (UB) \quad 4y \geq 3 \quad (LB)$$

- ▶ We have $\mathcal{L} = 3$, $a = 4$, $\mathcal{U} = 3x + 3$, $b = 5$
- ▶ Check $4x = 3 + i$ for $i \in [0, \frac{4 \cdot 5 - 4 \cdot 3}{5}]$ (i.e., $i \in [0, 1]$)
- ▶ Satisfiable for $i = 1 \Rightarrow$ has solutions!

Example, cont

Geometrically:

An Optimization

- ▶ Omega test uses important optimization to handle equality constraints
- ▶ Equality constraints can be expressed as pair of inequalities, but handling equalities directly much more efficient
- ▶ Thus, Omega test handles equality constraints in a special way
- ▶ Uses interesting coefficient-reducing technique based on **symmetric modulo**
- ▶ Details are in paper posted on class webpage

Omega Test Summary

- ▶ Omega test is an **elimination-based technique** for solving linear inequalities over integers
- ▶ Constructs three kinds of projections: real shadow, dark shadow, gray shadow
- ▶ Problem has no solution if real shadow has no solution
- ▶ Problem has solution if dark shadow has solution
- ▶ Otherwise, problem has solution iff one of the dark shadows has solution
- ▶ Omega test handles equalities specially using the symmetric modulo technique
